1.Introduction

Code comments are an integral part of a code. They improve program comprehension .The lack of code comments is a common problem to understand a unknown code. Therefore, it is beneficial to generate code comments automatically. In this project, it is proposed a general approach to generate code comments automatically by analyzing codes.

The project implementation is started with collecting the first year students' code of BSSE 10th batch .Then, the project will be implemented with two main tasks:-

1. Commenting on functional blocks of an uncommented source code.
2. Commenting after finding similarities between uncommented and commented source code.

1.1. Background study

Lexical analysis

Lexical analysis, lexing or tokenization is the process of converting a sequence of characters (such as in a computer program or web page) into a sequence of tokens (strings with an assigned and thus identified meaning). A program that performs lexical analysis may be termed a *lexer*, *tokenizer*, or *scanner*, though *scanner* is also a term for the first stage of a lexer. A lexer is generally combined with a parser which together analyze the syntax of programming. A *lexeme* is a sequence of characters in the source program that matches the pattern for a token and is identified by the lexical analyzer as an instance of that token.

Common token names are

- identifier: names the programmer chooses;
- keyword: names already in the programming language;
- separator (also known as punctuators): punctuation characters and paired-delimiters;
- operator: symbols that operate on arguments and produce results;
- literal: numeric, logical, textual, reference literals;
- comment: line, block.

Syntax

In programming, syntax refers to the rules that specify the correct combined sequence of symbols that can be used to form a correctly structured program using a given programming language. Programmers communicate with computers through the correctly structured syntax, semantics and grammar of a programming language.

Semantics

Semantics is a linguistic concept separate from the concept of syntax, which is also often related to attributes of computer programming languages. The idea of semantics is that the linguistic representations or symbols support logical outcomes, as a set of words and phrases signify ideas to both humans and machines.

Abstract Syntax Tree

An abstract syntax tree (AST), or just syntax tree, is a tree representation of the abstract syntactic structure of source code written in a programming language. Each node of the tree denotes a construct occurring in the source code. The syntax is "abstract" in the sense that it does not represent every detail appearing in the real syntax, but rather just the structural, content-related details. For instance, grouping parentheses are implicit in the tree structure, and a syntactic construct like an if-condition-then expression may be denoted by means of a single node with three branches.

Figure 1: Abstract Syntax Tree

1.2 Challenges

Implementing a new software solution carries with it a number of challenges. The process can be overwhelming, confusing and lengthy. Implementing this project there are lot of challenges that I have faced. Some of them are:-

- Handling large code for the first time
- Learning and understanding algorithm
- Reading Abstract Syntax Tree
- Reading Syntactically similarity

- Implementing Abstract Syntax Tree
- Matching similarity of two code

2. Project Overview

I have divided my whole project into four different parts. They are:-

- Commenting on functional blocks
- Implementation of syntactically similarity
- Implementation of semantically similarity
- Implementation of Abstract Syntax Tree

3. User Manual

3.1 Commenting on functional blocks

Input Function:-

```
void partition(int *arr,int low,int high)
```

```
{  
  
    int pivot,temp,i,j;  
  
    pivot=arr[high];  
  
    for(i=low-1,j=low;j<high;j++)  
  
    {  
  
        if(arr[j]<pivot)  
  
        {  
  
            i+=1;  
  
            temp=arr[j];  
  
            arr[j]=arr[i];  
  
            arr[i]=temp;  
  
        }  
  
    }  
  
    temp=arr[high];  
  
    arr[high]=arr[i+1];  
  
    arr[i+1]=temp;  
  
    return i+1;  
  
}
```

Output Function:-

void partition(int *arr,int low,int high)//The name of the function is ***partition***.The return type of the function is ***void***.The parameters of the function respectively are (*arr,low,high) and the data type of the parameters respectively are (int,int,int).

```
{  
  
    int pivot,temp,i,j;
```

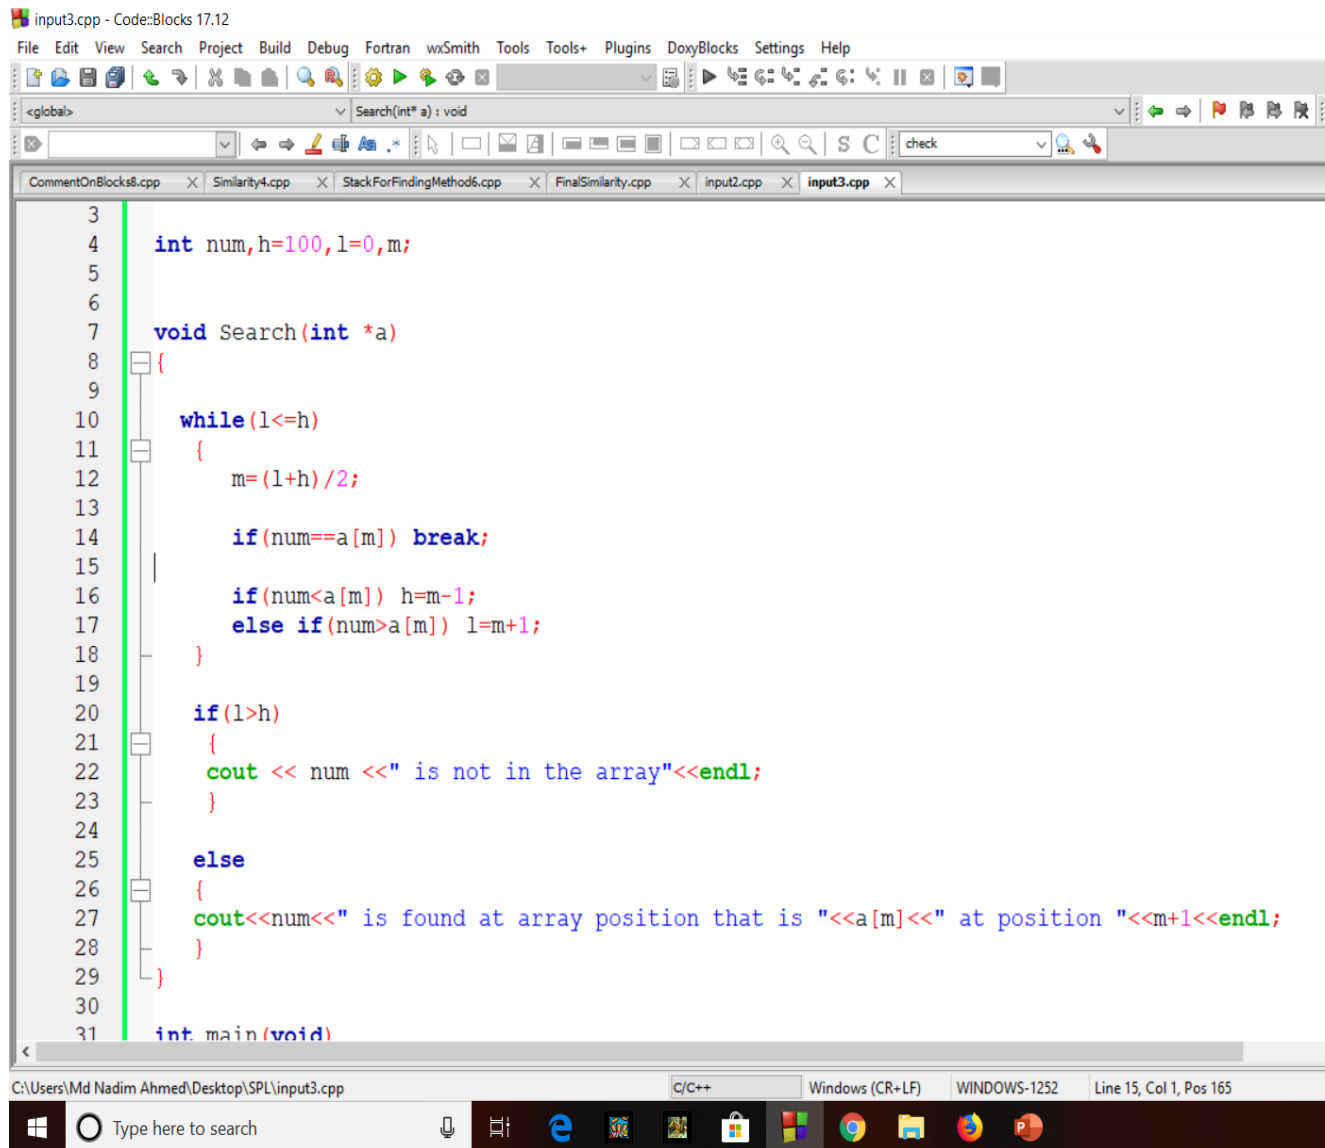

```
pivot=arr[high];
```

for(j=low-1,j=100;j++)//This is a for loop which starts with 1 and ends with till the value .The for loop is incremental. The variable name is `***i***` and the data type of the variable is `***int***`.

```
{  
    if(arr[j]<pivot)  
    {  
  
        i+=1;  
        temp=arr[j];  
        arr[j]=arr[i];  
        arr[i]=temp;  
    }  
}  
temp=arr[high];  
arr[high]=arr[i+1];  
arr[i+1]=temp;  
return i+1;  
}
```

3.2 Syntactically Similarity

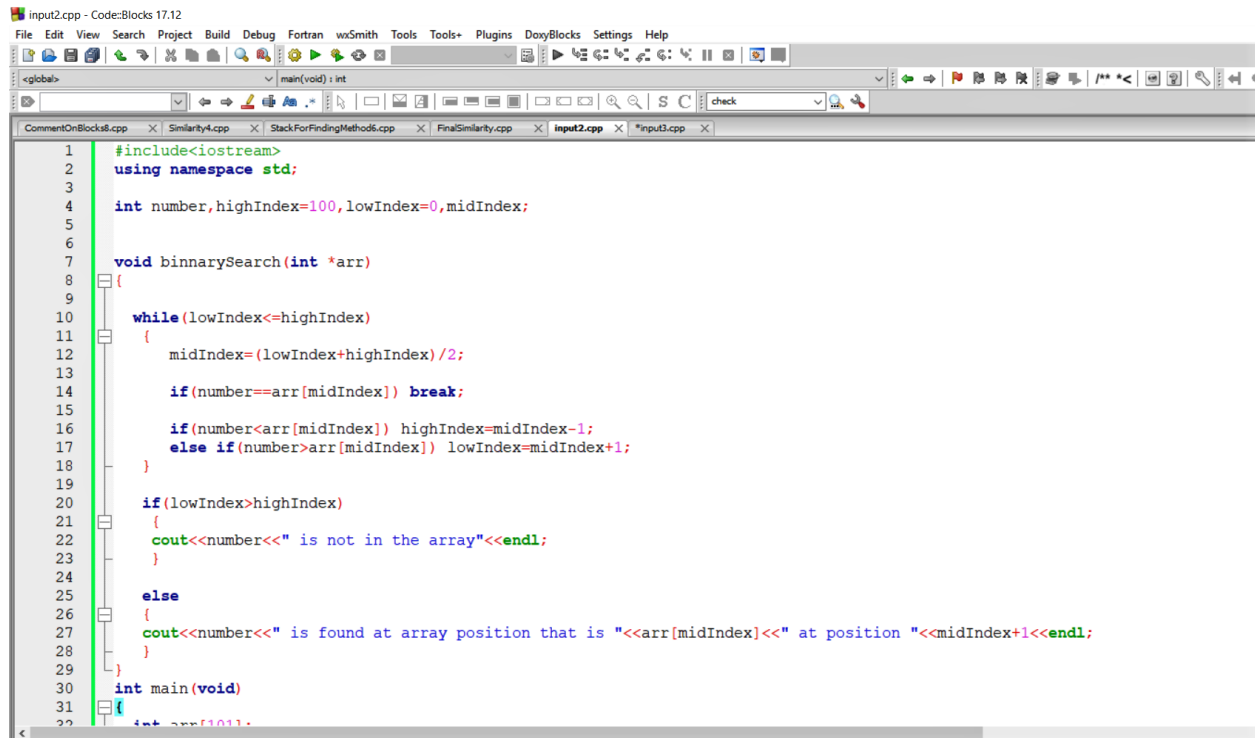

This similarity is implemented by using string of two source codes. Then the both strings are compared with edit distance algorithm.

```
3
4  int num,h=100,l=0,m;
5
6
7  void Search(int *a)
8  {
9
10     while(l<=h)
11     {
12         m=(l+h)/2;
13
14         if(num==a[m]) break;
15
16         if(num<a[m]) h=m-1;
17         else if(num>a[m]) l=m+1;
18     }
19
20     if(l>h)
21     {
22         cout << num << " is not in the array"<<endl;
23     }
24
25     else
26     {
27         cout<<num<< " is found at array position that is "<<a[m]<< " at position "<<m+1<<endl;
28     }
29 }
30
31 int main(void)
```

C:\Users\Md Nadim Ahmed\Desktop\SPL\input3.cpp C/C++ Windows (CR+LF) WINDOWS-1252 Line 15, Col 1, Pos 165

Figure 2:User manual: Input 1

The screenshot shows the Code::Blocks IDE with the file 'input2.cpp' open. The code implements a binary search algorithm. It includes the `<iostream>` header and uses the `std` namespace. A variable `number` is declared, and `highIndex` is set to 100, `lowIndex` to 0, and `midIndex` is also declared. The `binnarySearch` function (note the typo) takes an array `arr` as a parameter. It uses a `while` loop to search for the `number` in the array. If the number is found, it prints the position. If not, it prints a message stating the number is not in the array. The `main` function is also shown, starting with the declaration of the array `arr`.

```
1  #include<iostream>
2  using namespace std;
3
4  int number,highIndex=100,lowIndex=0,midIndex;
5
6
7  void binnarySearch(int *arr)
8  {
9
10     while(lowIndex<=highIndex)
11     {
12         midIndex=(lowIndex+highIndex)/2;
13
14         if(number==arr[midIndex]) break;
15
16         if(number<arr[midIndex]) highIndex=midIndex-1;
17         else if(number>arr[midIndex]) lowIndex=midIndex+1;
18     }
19
20     if(lowIndex>highIndex)
21     {
22         cout<<number<<" is not in the array"<<endl;
23     }
24
25     else
26     {
27         cout<<number<<" is found at array position that is "<<arr[midIndex]<<" at position "<<midIndex+1<<endl;
28     }
29 }
30
31 int main(void)
32 {
33     int arr[101];
```

Figure 4:Output of Syntactically Similarity

3.3 Sementically Similarity

This similarity is implemented by splitting the functions of two codes. Then the functions are concatenated with a main function format. By using a function named “system”, the codes are run from the terminal and got output.If the output of both codes are same for same input.Then, we can tell that the codes are syntactically similar.

```
148 void binnarySearch(int *arr)
149 {
150     while(lowIndex<=highIndex)
151     {
152         midIndex=(lowIndex+highIndex)/2;
153         if(number==arr[midIndex]) break;
154         if(number<arr[midIndex]) highIndex=midIndex-1;
155         else if(number>arr[midIndex]) lowIndex=midIndex+1;
156     }
157     if(lowIndex>highIndex)
158     {
159         cout<<number<<" is not in the array"<<endl;
160     }
161     else
162     {
163         cout<<number<<" is found at array position that is "<<arr[midIndex]<<" at position "<<midIndex+1<<endl;
164     }
165 }

4. Conclusion

Implementing this project helps me to improve my coding skill and I have learned to handle large code for the first time. I hope it will help me to deal with difficulties in future. This project was quiet challenging and I gained a lot of experience from it. I want to thank my supervisor for guiding me a lot during this project.

Appendix

In this project, I have implemented auto-commenting in a source code for first year student's code. In future, I want to implement this project for a large code
